(3) Data center efficiencies

Data centers ex-IT have continued to become less power intensive, but the pace of efficiency gains appears to have considerably slowed. Relative to 2015 baseline, we see avoided carbon dioxide emissions from data centers of 1,000-2,000 million tons in 2030 in our updated analysis. Notably, much of the avoided emissions were based on 2015-19 efficiency gains. Demand growth is currently more than offsetting power efficiency, driving higher expected emissions. A re-acceleration of efficiencies to levels greater than our base case could mitigate the emissions growth we forecast, and we note corporate optimism that this can be done.

QA Dataset

QA Data Generated by GPT-4o

Question: What equipment is shown in the image?

Answer: The image shows a transformer with cooling fins for heat dissipation and associated wiring, which appears properly connected.
